Chapter 4: outline

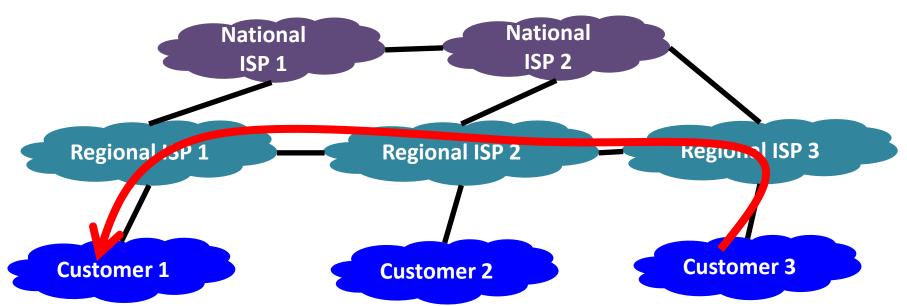

- 4.1 Introduction
- 4.2 Virtual circuit and datagram networks
- 4.3 What's inside a router
- 4.4 IP: Internet Protocol
 - Datagram format
 - IPv4 addressing
 - Network AddressTranslation (NAT)
 - DHCP
 - ICMP
 - IPv6
 - IPsec

- 4.5 Routing algorithms
 - Link state
 - Distance vector
 - Hierarchical routing
- 4.6 Routing in the Internet
 - RIP
 - OSPF
 - BGP
- 4.7 Broadcast and multicast routing

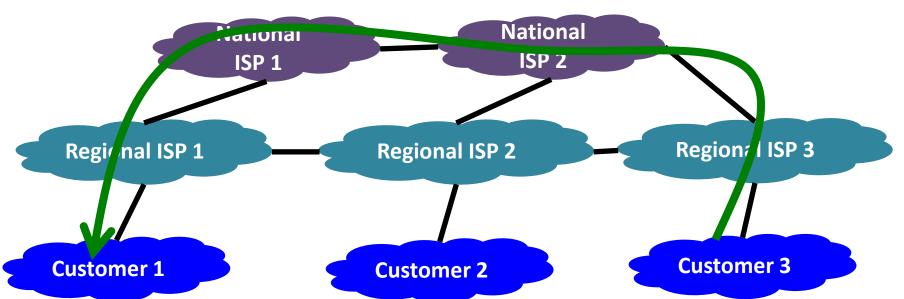

- Problems with always taking shortest path:
 - All traffic must travel on shortest path
 - All nodes must do same link cost calculation
 - Not possible to enforce various business rules

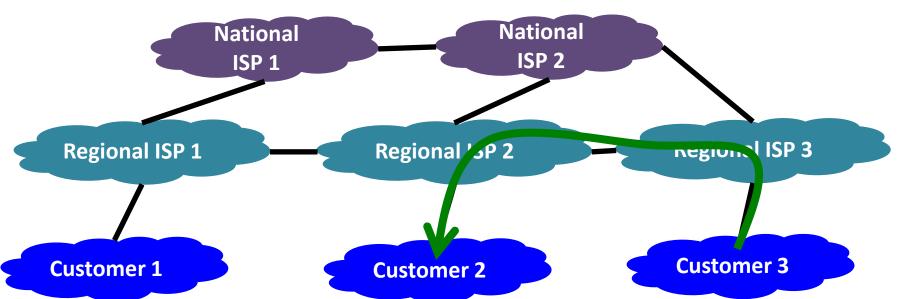

- Example: customer 3 talking to customer 1
 - Shortest path transits Regional ISP 2
 - Regional ISP 2 isn't being paid by either customer

- Example: customer 3 talking to customer 1
 - Goes through National ISP 1 & 2
 - Regional 3 is paying National ISP 2
 - Regional 1 is paying National ISP 1

- Example: customer 3 talking to customer 2
 - Regional 2 and 3 are peered
 - Avoid going through National ISP 2 since then both regionals would incur expense

Other routing issues

- Routing policies may need to handle a variety of constraints:
 - Political, security, or economic
 - Some examples (Tanenbuam):
 - Don't carry commercial traffic on educational network
 - Never send Pentagon traffic through Iraq
 - Use TeliaSonera instead of Verizon because it is cheaper
 - Don't use AT&T in Australia because performance is poor
 - Traffic starting or ending at Apple should not transit Google

Link-state, disadvantages

- Floods topology information
 - High bandwidth and storage requirements
 - Nodes divulge potentially sensitive information
- Entire path computed locally
 - High processing overhead for large network
- Distance calculation hides information
 - Everyone has to have a shared notion of link cost
- Typically used within one organization
 - Autonomous System (AS)
 - e.g. university, company, ISP
 - Popular link-state protocols: OSPF, IS-IS

Distance-vector

Disadvantages:

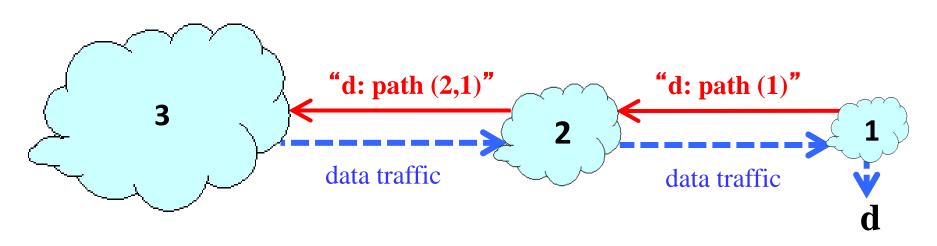

- Count to infinity, "bad news travels slow"
- Slow to converge
- Hides information that you might need in an inter-AS setting

Advantages:

- Summarizes details of network topology
 - Trades optimality for scalability
- Each node only needs to know about next hop

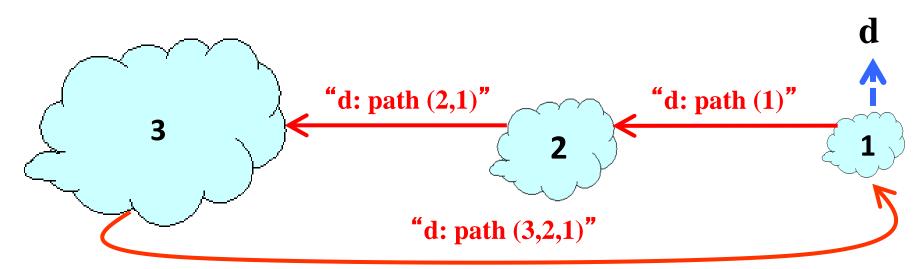

Path-vector routing

- Extension of distance-vector
 - Support flexible routing policies
 - Avoid count-to-infinity problem
- Key idea: advertise the entire path
 - Distance vector: send distance metric per destination d
 - Path vector: send the entire path per destination d

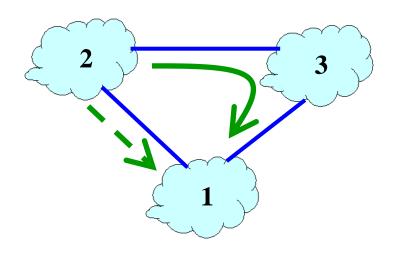

Detecting loops

- Path-vector can easily detect loops
 - Look for your own node ID in the path
 - e.g. node 1 sees itself in path "3, 2, 1"
- Node can discard paths with loops
 - e.g. node 1 drops advertisement from 3

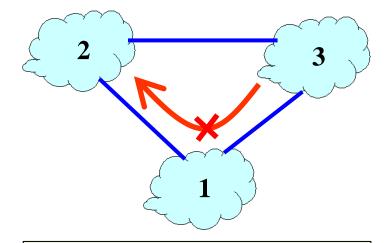

Flexible routing policies

- Each node can apply local policies:
 - Path selection: Which path to use?
 - Path export: Which path to advertise?

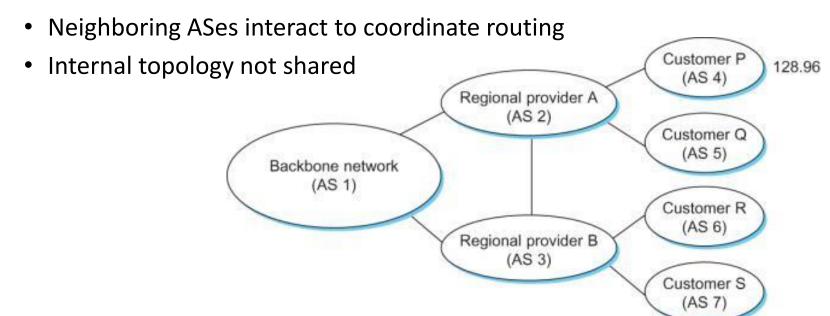

Node 2 may prefer the path "2, 3, 1" over the path "2, 1". Perhaps it is cheaper.

Node 1 may not export the path "1, 2". Perhaps node 1 reserves the 1->2 link for special traffic.

Scaling up and up

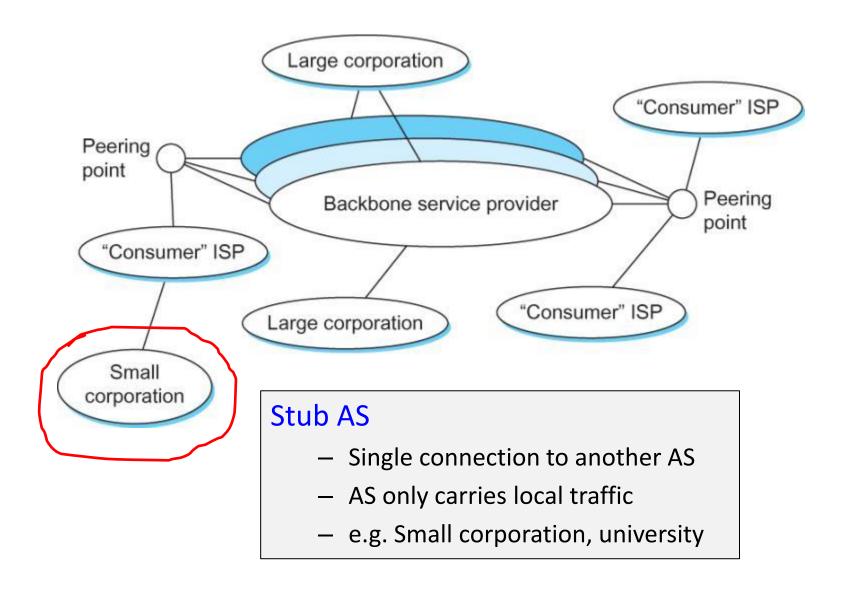

- How to scale to the global Internet?
 - Add another level of hierarchy!
 - Routing amongst Autonomous Systems (ASes)
 - Distinct regions of admin control
 - Routers/links managed by a single institution
 - ASes can use policy-based routing
 - Interaction between ASes

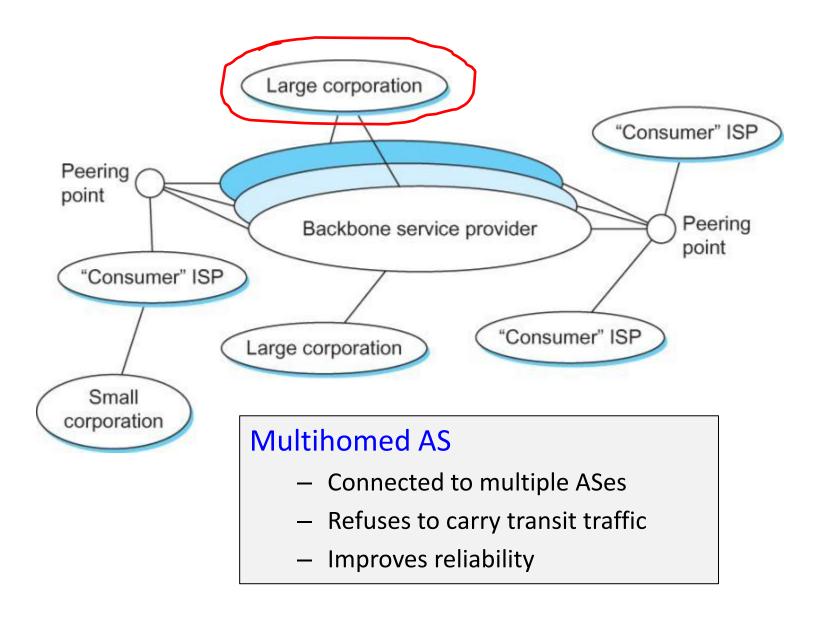

Autonomous System Numbers

- Each AS assigned a unique number
 - Before 2007: AS Numbers 16-bit
 - After 2007: IANA began allocating 32-bit AS numbers
 - Currently over 50,000 allocated
 - Level 3: 1
 - MIT: 3
 - Harvard: 11
 - Yale: 29
 - Princeton: 88
 - AT&T: 7018, 6341, 5074, ...
 - UUNET: 701, 702, 284, 12199, ...
 - Sprint: 1239, 1240, 6211, 6242, ...
 - ...

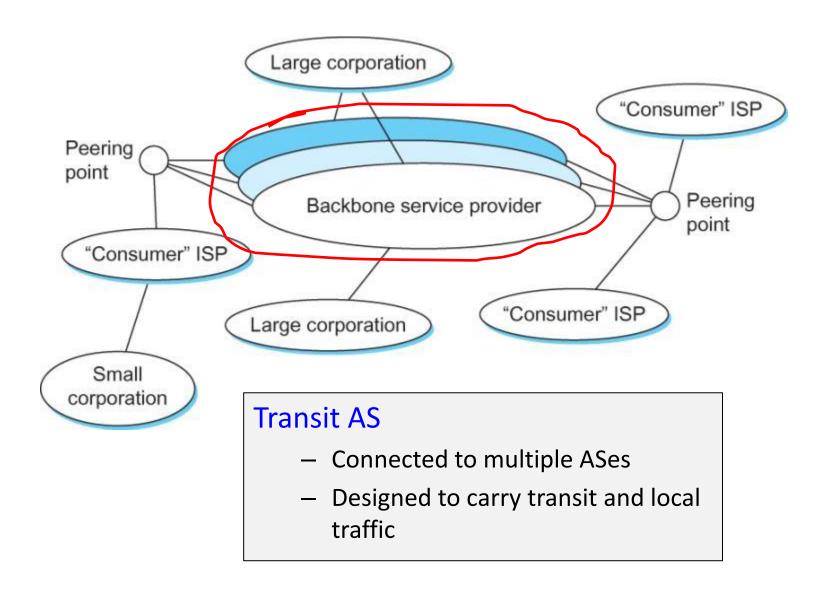

AS stub

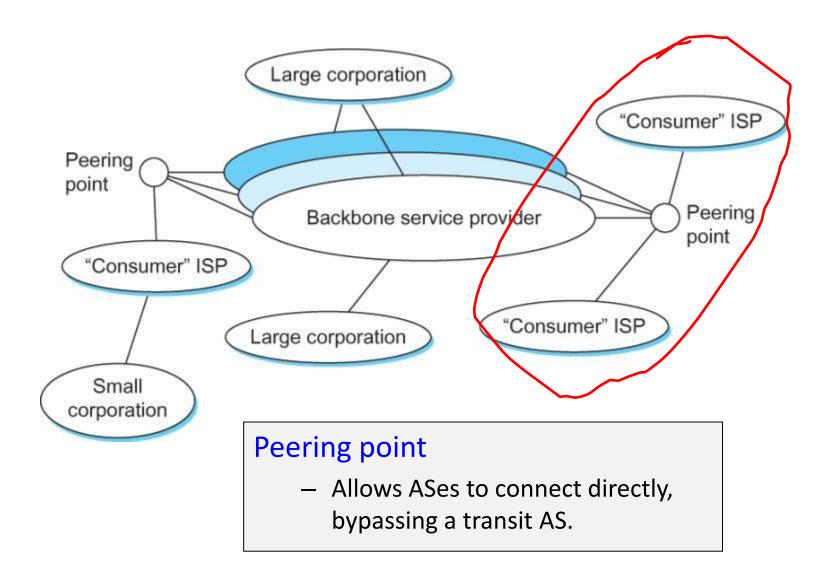

AS multihomed

AS transit

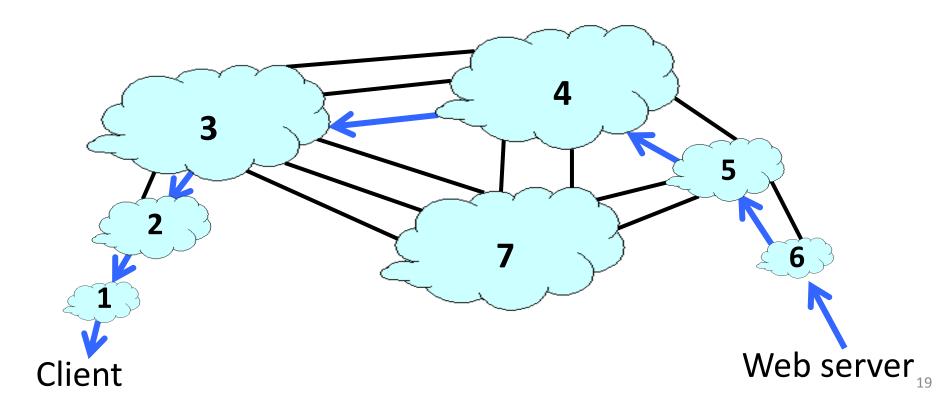

Peering point

Inter-AS routing

AS-level topology

- Destinations are IP prefixes (e.g. 12.0.0.0/8)
- Nodes are Autonomous Systems (ASes)
- Edges are links and business relationships

Inter-AS routing challenges

Scale:

– IP prefixes: 200,000+

ASes: 20K+ visible, 50k+ allocated

Routers: millions

• Privacy:

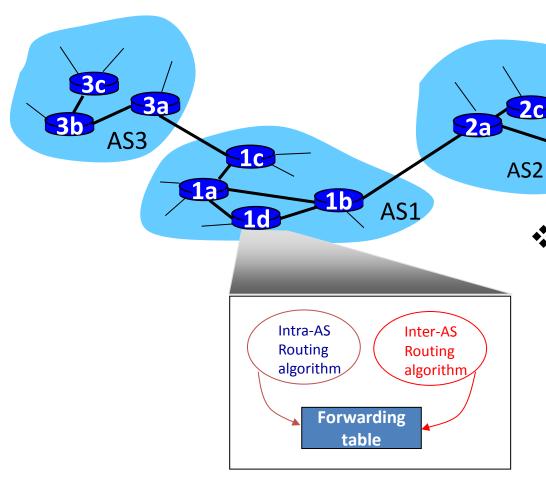

- ASes don't want others to known topology
- ASes don't want business relationships exposed

Policy:

- No internet-wide notion of link cost metric
- Need control over where you send traffic, who you send traffic through, etc.

Interconnected ASes

2b

Forwarding table configured by both intraand inter-AS routing algorithm

- Intra-AS sets entries for internal destinations
- Inter-AS & intra-AS sets entries for external destinations

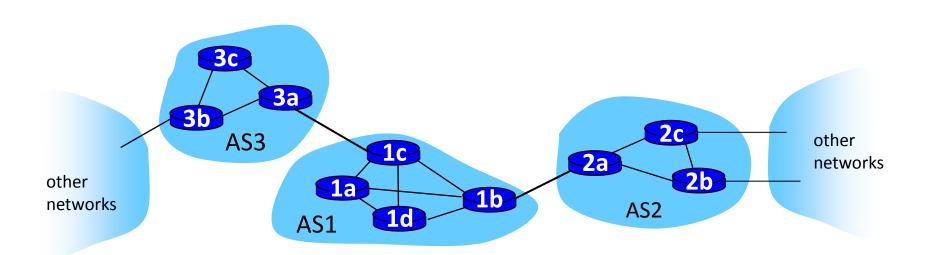

Inter-AS tasks

- Suppose router in AS1 receives datagram destined outside of AS1:
 - Router should forward packet to gateway router, but which one?

AS1 must:

- Learn which destinations are reachable through AS2, which reachable through AS3
- 2. Propagate this reachability info to all routers in AS1

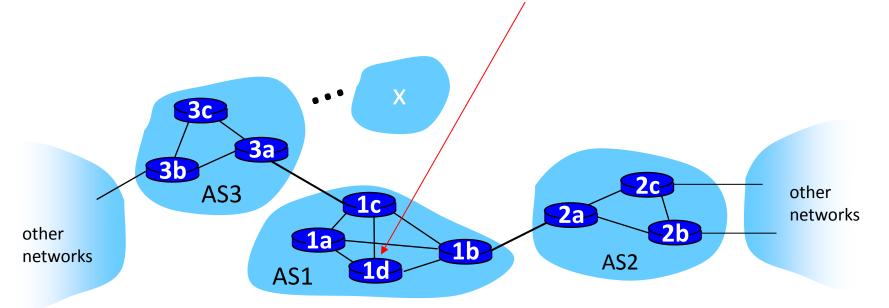

Job of inter-AS routing!

Setting forwarding table in router 1d

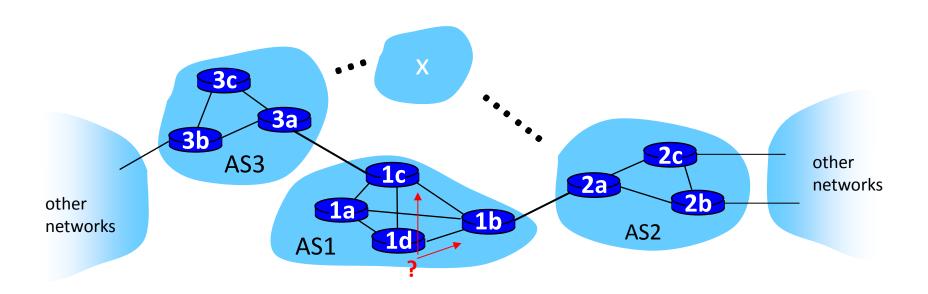

- ❖ AS1 learns that subnet x reachable via AS3 (gateway 1c), but not via AS2
 - Inter-AS protocol propagates info to all internal routers
- ❖ Router 1d determines from intra-AS routing info that its interface / is on the least cost path to 1c

Installs forwarding table entry (x,I)

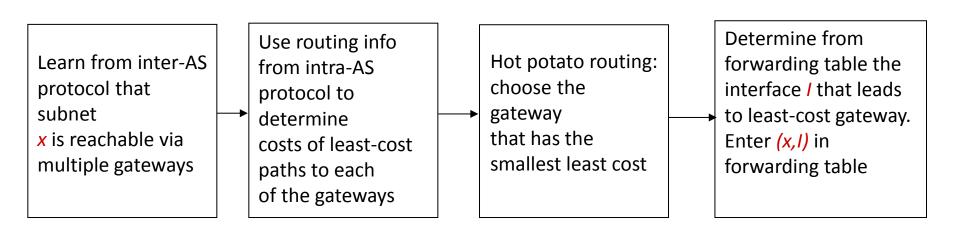

Choosing among multiple ASes

- Now suppose AS1 learns from inter-AS protocol that subnet *x* is reachable from AS3 *and* AS2.
- ❖ To configure forwarding table, router 1d must determine towards which gateway it should forward packets for dest x
 - This is also job of inter-AS routing protocol!

Choosing among multiple ASes

- Now suppose AS1 learns from inter-AS protocol that subnet *x* is reachable from AS3 *and* AS2.
- ❖ To configure forwarding table, router 1d must determine towards which gateway it should forward packets for dest x
 - This is also job of inter-AS routing protocol!
- Hot potato routing: send towards closest router

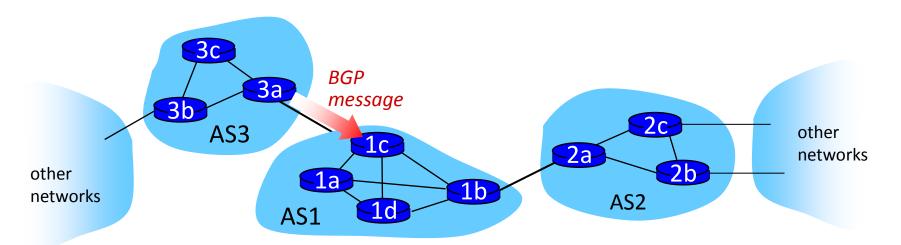

Internet inter-AS routing: BGP

- BGP (Border Gateway Protocol):
 - De facto inter-domain routing protocol
 - "glue that holds the Internet together"
- BGP allows each AS to:
 - eBGP: Obtain subnet reachability information from neighboring ASes
 - iBGP: Propagate reachability information to all ASinternal routers
 - Determine good routes to other networks based on reachability information and policy
 - Subnet to advertise its existence : "I am here"

BGP basics

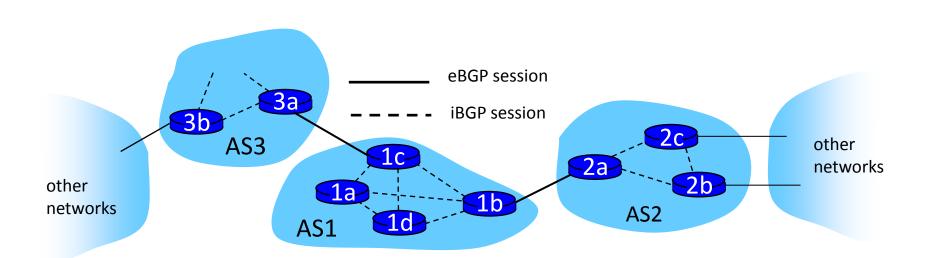

BGP session:

- Two BGP routers (peers) exchange BGP messages
- Path vector protocol, advertise paths to different prefixes
- Exchanged over semi-permanent TCP connections
- When AS3 advertises a prefix to AS1:
 - AS3 promises it will forward datagrams towards that prefix
 - AS3 can aggregate prefixes in its advertisement

BGP basics: distributing path info

- Using eBGP session between 3a and 1c, AS3 sends prefix reachability info to AS1.
 - 1c can then use iBGP to distribute new prefix to all routers in AS1
 - 1b can then re-advertise new reachability info to AS2 over 1b-to-2a eBGP session
- When router learns of new prefix, it creates entry for prefix in its forwarding table.

Path attributes and BGP routes

- Advertised prefix includes BGP attributes
 - prefix + attributes = route
 - AS-PATH: contains ASs through which prefix advertisement has passed: e.g., AS 67, AS 17
 - NEXT-HOP: indicates specific internal-AS router to next-hop
 AS
 - May be multiple links from current AS to next-hop-AS
- Gateway router uses import policy to accept/decline
 - e.g., never route through AS x
 - policy-based routing

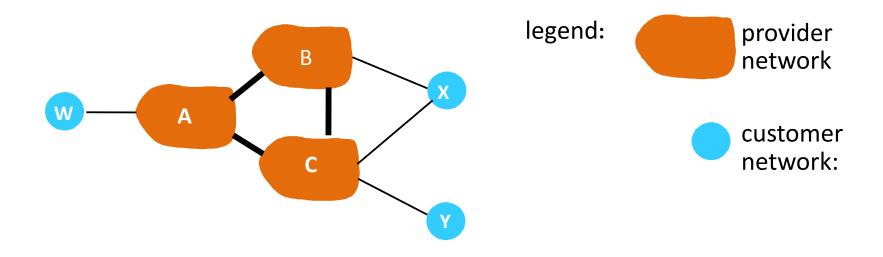

BGP route selection

- Router may learn about more than 1 route to destination AS
- Router selects route based on:
 - 1. Local preference value attribute: policy decision
 - Shortest AS-PATH
 - 3. Closest NEXT-HOP router: hot potato routing
 - 4. Additional criteria

BGP messages

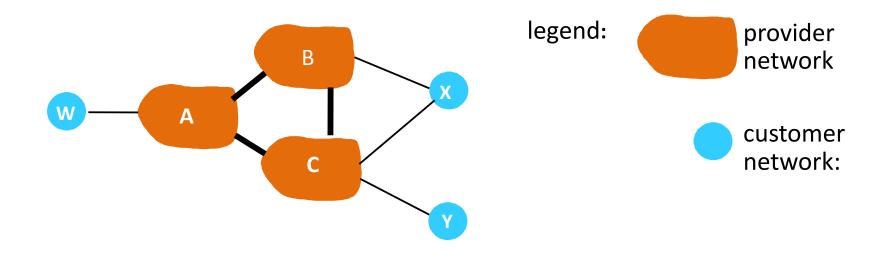

- BGP messages exchanged between peers over semipermanent TCP connection
- **❖** BGP messages:
 - OPEN: opens TCP connection to peer and authenticates sender
 - UPDATE: advertises new path (or withdraws old)
 - KEEPALIVE: keeps connection alive in absence of UPDATES; also ACKs OPEN request
 - NOTIFICATION: reports errors in previous msg; also used to close connection

BGP routing policy

- A,B,C are *provider networks*
- X,W,Y are customers (of provider networks)
- * X is *dual-homed:* attached to two networks
 - X does not want to route from B to C via itself
 - .. so X will not advertise to B a route to C

BGP routing policy (2)

- ❖ A advertises path AW to B
- ❖ B advertises path BAW to X
- Should B advertise path BAW to C?
 - No way! B gets no revenue for routing CBAW since neither W nor C are B's customers
 - B wants to force C to route to w via A
 - B wants to route only to/from its customers!

Intra-AS vs. Inter-AS routing

Policy:

- ❖ Inter-AS: Admin wants control over how its traffic routed, who routes through its net.
- Intra-AS: Single admin, so no policy decisions needed

Scale:

Hierarchical routing saves table size, reduced update traffic

Performance:

- Intra-AS: Can focus on performance
- Inter-AS: Policy may dominate over performance

Summary

- Inter-AS routing
 - Scaling routing to Internet scale
 - Routing between independent ASes
 - Allows routing to encode business rules
- Border Gateway Protocol (BGP)
 - A path vector protocol
 - The glue that holds the Internet together
