

# Built-in data types

logical AND	logical OR	logical NOT
&&		!

```
public static void main(String [] args)
```

# Overview

- Variables
  - Allows us to **store and compute on data**
  - For now we'll be using basic Java data types
    - String, int, double, boolean, char
  - Variables in Java must be declared including type!
  - Converting between different basic types
- Types of errors
  - Runtime, compile
- Random numbers
  - Allow us to simulate random events
  - Needed for loops assignment

# Variables and data types

- Variables
  - Stores information your program needs
  - Each has a unique name
  - Each has a specific type

Java built-in type	what it stores	example values	operations
<b>String</b>	sequence of characters	"Hello world!" "I love this!"	concatenate
<b>char</b>	characters	'a', 'b', '!'	compare
<b>int</b>	integer values	42 1234	add, subtract, multiply, divide, remainder
<b>double</b>	floating-point values	9.95 3.0e8	add, subtract, multiply, divide
<b>boolean</b>	truth values	true false	and, or, not

# Some definitions

## Declaration statement

“I'm going to need an integer and let's call it a”

NOTE: in Java you are *required* to declare a variable before using it!

```
int a;
```

## Variable name

“Whenever I say a, I mean the value stored in a”

```
a = 10;
```

## Literal

“I want the value 10”

```
int b;
```

```
b = 7;
```

## Assignment statement

“Variable b gets the literal value 7”

```
int c = a + b;
```

## Combined declaration and assignment

“Make me an integer variable called c and assign it the value obtained by adding together a and b”

= in CS  
is not the same as  
= in math!

# Text

- String data type
  - A sequence of characters
  - Double quote around the characters
  - Concatenation using the + operator

```
String firstName = "Keith";  
String lastName = "Vertanen";  
String fullName = firstName + " " + lastName;  
String favNumber = "42";  
  
System.out.println(fullName +  
    "'s favorite number is " +  
    favNumber);
```

```
Keith Vertanen's favorite number is 42
```

# Characters

- **char data type**
  - Holds a single character
  - Single apostrophe, e.g. 'a', 'z'

```
public class CharExample
{
    public static void main(String [] args)
    {
        char ch1 = 'y';
        char ch2 = 'o';
        String result = "" + ch1;

        result = result + ch2;
        result = result + ch2;
        result = result + ch2;

        System.out.println(result);
    }
}
```

Double quotes with nothing in between, an empty String

```
% java CharExample
yooo
```

# Integers

- **int data type**

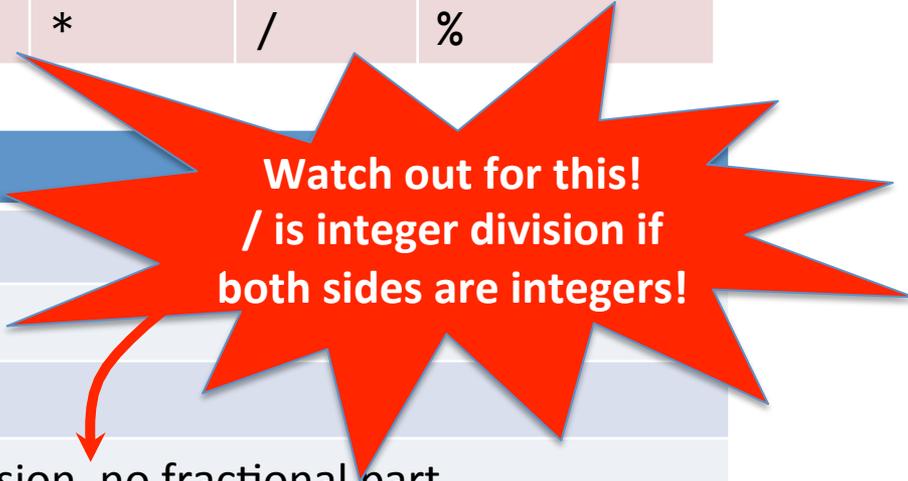

- An integer value between  $-2^{31}$  and  $+2^{31}-1$

- Between -2,147,483,648 and 2,147,483,647

- Operations:

add	subtract	multiply	divide	remainder
+	-	*	/	%

example	result	comment
10 + 7	17	
10 - 7	3	
10 * 7	70	
10 / 7	1	integer division, no fractional part
10 % 7	3	remainder after dividing by 7
10 / 0		runtime error, you can't divide an integer by 0!

**Watch out for this!**  
**/ is integer division if both sides are integers!**

# Integers

- **int data type**

- Normal rules of mathematical precedence

- e.g. multiplication/division before addition/subtraction

- Use ()'s to force a different order of calculation

example	result	comment
$10 + 7 * 2$	24	multiplication comes before addition
$(10 + 7) * 2$	34	()'s force addition to occur first
$10 / 7 + 2$	3	integer division result is 1 which is added to 2
$10 - 7 - 2$	1	
$(10 - 7) - 2$	1	
$10 - (7 - 2)$	5	

# Floating-point numbers

- `double` data type

- Floating-point number (as specified by IEEE 754)

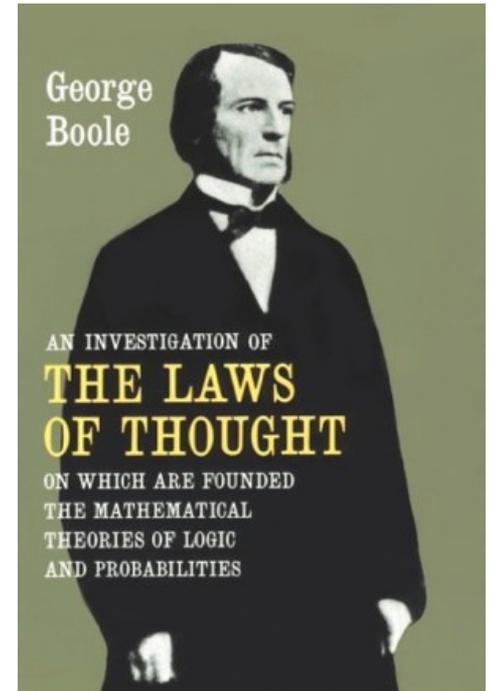

- Operations:

add	subtract	multiply	divide
+	-	*	/

example	result
<code>9.95 + 2.99</code>	<code>12.94</code>
<code>1.0 - 2.0</code>	<code>-1.0</code>
<code>1.0 / 2.0</code>	<code>0.5</code>
<code>1.0 / 3.0</code>	<code>0.3333333333333333</code>
<code>1.0 / 0.0</code>	<code>Infinity</code>
<code>0.0 / 123.45</code>	<code>0.0</code>
<code>0.0 / 0.0</code>	<code>NaN</code>

# Booleans

- **boolean data type**
  - Either true or false
  - Controls logic and flow of control in programs
  - Operations:

logical AND	logical OR	logical NOT
<code>&amp;&amp;</code>	<code>  </code>	<code>!</code>

Note: two symbols for logical AND and OR, not one!

# Booleans

- boolean data type

logical AND	logical OR	logical NOT
&&		!

`!a` → “Is a set to false?”

`a && b` → “Are both a *and* b set to true?”

`a || b` → “Is either a *or* b (or both) set to true?”

a	!a
true	false
false	true

a	b	a && b	a    b
false	false	false	false
false	true	false	true
true	false	false	true
true	true	true	true

# Comparisons

- Given two numbers → return a **boolean**

operator	meaning	true example	false example
==	equal	7 == 7	7 == 8
!=	not equal	7 != 8	7 != 7
<	less than	7 < 8	8 < 7
<=	less than or equal	7 <= 7	8 <= 7
>	greater than	8 > 7	7 > 8
>=	greater than or equal	8 >= 2	8 >= 10

Is the sum of a, b and c equal to 0?

`(a + b + c) == 0`

Is grade in the B range?

`(grade >= 80.0) && (grade < 90.0)`

Is sumItems an even number?

`(sumItems % 2) == 0`

# Leap year example

- Years divisible by 4 but not by 100 → leap year
- Years divisible by 400 → leap year

```
public class LeapYear
{
    public static void main(String [] args)
    {
        int year = Integer.parseInt(args[0]);
        boolean isLeapYear;

        // Leap year if divisible by 4 but not by 100
        isLeapYear = (year % 4 == 0) && (year % 100 != 0);

        // But also leap year if divisible by 400
        isLeapYear = isLeapYear || (year % 400 == 0);
        System.out.println(isLeapYear);
    }
}
```

```
% java LeapYear 2000
true
```

# Type conversion

- Java is strongly typed
  - Helps protect you from mistakes (aka "bugs")

```
public class TypeExample0
{
    public static void main(String [] args)
    {
        int orderTotal = 0;
        double costItem = 29.95;

        orderTotal = costItem * 1.06;
        System.out.println("total=" + orderTotal);
    }
}
```

```
% javac TypeExample0.java
TypeExample0.java:7: possible loss of precision
found    : double
required: int
    orderTotal = costItem * 1.06;
                        ^
```

# Type conversion

- Converting from one type to another:
  - Manually → **using a cast**
    - A cast is accomplished by putting a type inside ()'s
  - Casting to int drops fractional part
    - **Does not round!**

```
public class TypeExample1
{
    public static void main(String [] args)
    {
        int orderTotal = 0;
        double costItem = 29.95;

        orderTotal = (int) (costItem * 1.06);

        System.out.println("total=" + orderTotal);
    }
}
```

```
% java TypeExample1
total=31
```

# Type conversion

- Automatic conversion
  - Numeric types:
    - If **no loss of precision** → automatic promotion

```
public class TypeExample2
{
    public static void main(String [] args)
    {
        double orderTotal = 0.0;
        int costItem = 30;

        orderTotal = costItem * 1.06;

        System.out.println("total=" + orderTotal);
    }
}
```

```
% java TypeExample2
total=31.8
```

# Type conversion

- Automatic conversion
  - String concatenation using the + operator converts numeric types to also be a String

```
public class TypeExample3
{
    public static void main(String [] args)
    {
        double costItem = 29.95;

        String message = "The widget costs ";
        message = message + costItem;
        message = message + "!";

        System.out.println(message);
    }
}
```

```
% java TypeExample3
The widget costs 29.95!
```

# args array

Program input comes in  
as Strings from  
command line (for now)

```
public static void main(String [] args)
```

```
% java CostCalc bananas 12 0.21  
To buy 12 bananas you will need $2.52
```

identifier	meaning	value	type
args[0]	1 <sup>st</sup> thing on command line after Java class name	"bananas"	String
args[1]	2 <sup>nd</sup> thing on command line	"12"	String
args[2]	3 <sup>rd</sup> thing on command line after Java class	"0.21"	String
args.length	# of things on command line	3	int

# Static methods

- Java has lots of **helper methods**
  - Things that take value(s) and return a result
    - e.g. Math functions
    - e.g. Type conversion: `String` → `int`  
`String` → `double`
    - e.g. Random number generation
- For now, we'll stick to **static** methods
  - Live in some particular Java class
    - e.g. `Math`, `Integer` or `Double`
  - Call using class name followed by dot

# Converting text to a numeric type

method	description
<code>Integer.parseInt(String a)</code>	converts text a into an int
<code>Double.parseDouble(String a)</code>	convert text a into a double

```
public class CostCalc
{
    public static void main(String [] args)
    {
        String product = args[0];
        int qty = Integer.parseInt(args[1]);
        double cost = Double.parseDouble(args[2]);

        double total = qty * cost;

        System.out.print("To buy " + qty);
        System.out.print(" " + product);
        System.out.println(" you will need $" + total);
    }
}
```

```
% java CostCalc elections 2 1e6
To buy 2 elections you will need $2000000.0
```

# Different types of errors: runtime

runtime error

```
% java CostCalc apples 6 -10  
To buy 6 apples you will need $-60.0
```

```
% java CostCalc apples 6 foo  
Exception in thread "main" java.lang.NumberFormatException: For input string: "foo"  
    at sun.misc.FloatingDecimal.readJavaFormatString  
        (FloatingDecimal.java:1222)  
    at java.lang.Double.parseDouble(Double.java:510)  
    at CostCalc.main(ArgsExample.java:7)
```

```
% java CostCalc apples 6.1 0.25  
Exception in thread "main" java.lang.NumberFormatException: For input string: "6.1"

```

# Randomness

- Simulate roll of two 6-sided dice
- Generate two random #'s between 1 and 6

`Math.random()`

→ number in `[0, 1.0)`  
e.g. 0.0, 0.312, 0.9999999

`Math.random()*6`

→ number in `[0, 6.0)`  
e.g. 0.0, 1.872, 5.9999999

`(Math.random()*6)+1`

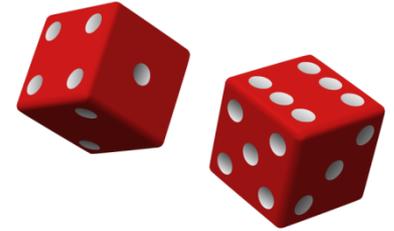

→ number in `[1, 7.0)`  
e.g. 1.0, 2.872, 6.9999999

`(int)(Math.random()*6)+1` → number in set `{1, 2, 3, 4, 5, 6}`  
e.g. 1, 2, 6

# Randomness

- Simulate roll of two 6-sided dice
- Generate two random #'s between 1 and 6

```
public class TwoDice
{
    public static void main(String [] args)
    {
        int dice1 = (int) (Math.random() * 6) + 1;
        int dice2 = (int) (Math.random() * 6) + 1;
        int sum    = dice1 + dice2;

        System.out.println(dice1 + " + " +
                           dice2 + " = " +
                           sum);
    }
}
```

```
% java TwoDice
3 + 4 = 7
% java TwoDice
1 + 6 = 7
% java TwoDice
1 + 1 = 2
```

# Type conversion quiz

- Automatic: **no loss of precision**
  - **int** will convert to a **double** if need be
  - **double** cannot automatically convert to **int**
- Manual: **cast** or using a **method**

expression	resulting type	resulting value
<code>(int) 3.14159</code>		
<code>Math.round(3.6)</code>		
<code>2 * 3.0</code>		
<code>2 * (int) 3.0</code>		
<code>(int) 2 * 3.0</code>		

# Type conversion quiz

- Automatic: **no loss of precision**
  - **int** will convert to a **double** if need be
  - **double** cannot automatically convert to **int**
- Manual: **cast** or using a **method**

expression	resulting type	resulting value
<code>(int) 3.14159</code>	int	3
<code>Math.round(3.6)</code>	long	4
<code>2 * 3.0</code>	double	6.0
<code>2 * (int) 3.0</code>	int	6
<code>(int) 2 * 3.0</code>	double	6.0

# String conversion quiz

- String conversion, using:
  - `Integer.parseInt()`
  - `Double.parseDouble()`

expression	resulting type	resulting value
<code>Integer.parseInt("30")</code>		
<code>Double.parseDouble("30")</code>		
<code>Integer.parseInt("30.1")</code>		
<code>Double.parseDouble("30.1")</code>		
<code>Integer.parseInt("\$30")</code>		
<code>Double.parseDouble(3.14)</code>		

# String conversion quiz

- String conversion, using:
  - `Integer.parseInt()`
  - `Double.parseDouble()`

expression	resulting type	resulting value
<code>Integer.parseInt("30")</code>	<code>int</code>	30
<code>Double.parseDouble("30")</code>	<code>double</code>	30.0
<code>Integer.parseInt("30.1")</code>	(runtime error, can't parse as int)	
<code>Double.parseDouble("30.1")</code>	<code>double</code>	30.1
<code>Integer.parseInt("\$30")</code>	(runtime error, can't parse as int)	
<code>Double.parseDouble(3.14)</code>	(compile error, 3.14 not a String)	

# String concatenation quiz

- + is addition for numeric types
- + is concatenation for String type
- numeric types convert to String if needed
  - Strings never (automatically) go back to number

expression	resulting type	resulting value
"testing " + 1 + 2 + 3		
"3.1" + 4159		
"2" + " + " + "3"		
1 + 2 + 3 + "66"		

# String concatenation quiz

- + is addition for numeric types
- + is concatenation for String type
- numeric types convert to String if needed
  - Strings never (automatically) go back to number

expression	resulting type	resulting value
"testing " + 1 + 2 + 3	String	"testing 123"
"3.1" + 4159	String	"3.14159"
"2" + " + " + "3"	String	"2 + 3"
1 + 2 + 3 + "66"	String	"666"

# Summary

- Variables
  - Allows us to **store and compute on data**
  - String, int, double, boolean, char
  - **Boolean operators** for logic and program flow control (more on this next time!)
- Type conversion
  - **Automatic**
    - e.g. int converting itself to a double
  - Explicit via **cast** or **method call**
  - Important!
    - **Cause of many, many, many software bugs**
