## Hidden Markov Models (HMMs)

# Pacman – Sonar (P4)

[Demo: Pacman – Sonar – No Beliefs(L14D1)]

## **Probability Recap**

Conditional probability

$$P(x|y) = \frac{P(x,y)}{P(y)}$$

Product rule

$$P(x,y) = P(x|y)P(y)$$

Chain rule

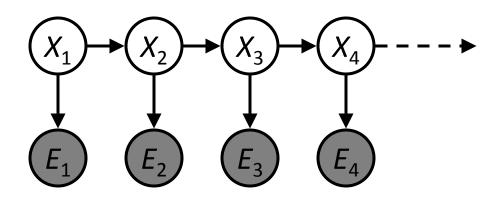

$$P(X_1, X_2, \dots X_n) = P(X_1)P(X_2|X_1)P(X_3|X_1, X_2)\dots$$
$$= \prod_{i=1}^n P(X_i|X_1, \dots, X_{i-1})$$

- X, Y independent if and only if:  $\forall x, y : P(x, y) = P(x)P(y)$
- lacksquare X and Y are conditionally independent given Z if and only if:  $X \!\perp\!\!\!\perp \!\!\!\perp \!\!\!\!\perp Y | Z$

$$\forall x, y, z : P(x, y|z) = P(x|z)P(y|z)$$

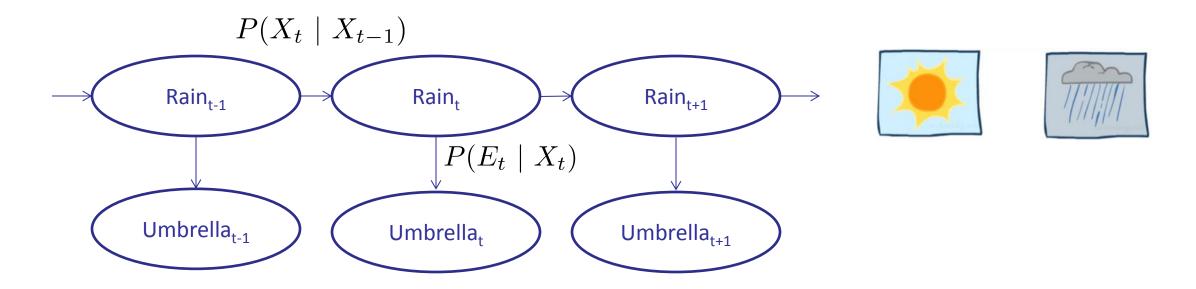

#### Hidden Markov Models

- Markov chains not so useful for most agents
  - Need observations to update your beliefs
- Hidden Markov models (HMMs)
  - Underlying Markov chain over states X
  - You observe outputs (effects) at each time step

### Example: Weather HMM

#### An HMM is defined by:

• Initial distribution:  $P(X_1)$ 

■ Transitions:  $P(X_t \mid X_{t-1})$ 

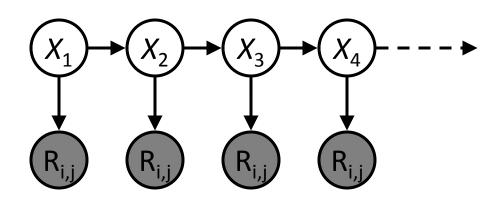

• Emissions:  $P(E_t \mid X_t)$ 

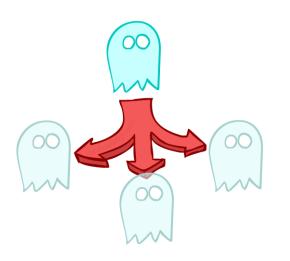

$R_{t}$	R <sub>t+1</sub>	$P(R_{t+1}   R_t)$
+r	+r	0.7
+r	-r	0.3
-r	+r	0.3
-r	-r	0.7

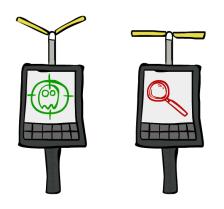

$R_{t}$	U <sub>t</sub>	$P(U_t   R_t)$
+r	+u	0.9
+r	-u	0.1
-r	+u	0.2
-r	-u	0.8

## Example: Ghostbusters HMM

- $P(X_1) = uniform$
- P(X|X') = usually move clockwise, but sometimes move in a random direction or stay in place
- $P(R_{ij}|X)$  = same sensor model as before: red means close, green means far away.

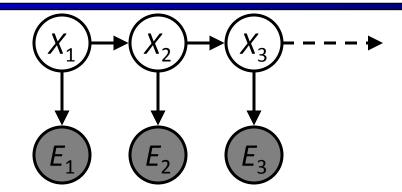

1/9	1/9	1/9
1/9	1/9	1/9
1/9	1/9	1/9

 $P(X_1)$ 

1/6	16	1/2
0	1/6	0
0	0	0

P(X | X' = <1,2>)

#### Joint Distribution of an HMM

Joint distribution:

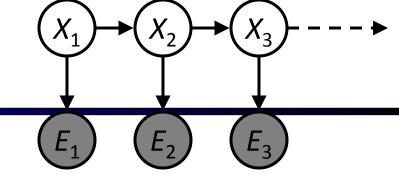

$$P(X_1, E_1, X_2, E_2, X_3, E_3) = P(X_1)P(E_1|X_1)P(X_2|X_1)P(E_2|X_2)P(X_3|X_2)P(E_3|X_3)$$

More generally:

$$P(X_1, E_1, \dots, X_T, E_T) = P(X_1)P(E_1|X_1) \prod_{t=2}^{T} P(X_t|X_{t-1})P(E_t|X_t)$$

- Questions to be resolved:
  - Does this indeed define a joint distribution?
  - Can every joint distribution be factored this way, or are we making some assumptions about the joint distribution by using this factorization?

#### Chain Rule and HMMs

• From the chain rule, *every* joint distribution over  $X_1, E_1, X_2, E_2, X_3, E_3$  can be written as:

$$P(X_1, E_1, X_2, E_2, X_3, E_3) = P(X_1)P(E_1|X_1)P(X_2|X_1, E_1)P(E_2|X_1, E_1, X_2)$$

$$P(X_3|X_1, E_1, X_2, E_2)P(E_3|X_1, E_1, X_2, E_2, X_3)$$

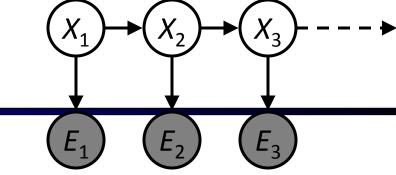

Assuming that

$$X_2 \perp\!\!\!\perp E_1 \mid X_1, \quad E_2 \perp\!\!\!\perp X_1, E_1 \mid X_2, \quad X_3 \perp\!\!\!\perp X_1, E_1, E_2 \mid X_2, \quad E_3 \perp\!\!\!\perp X_1, E_1, X_2, E_2 \mid X_3$$

gives us the expression posited on the previous slide:

$$P(X_1, E_1, X_2, E_2, X_3, E_3) = P(X_1)P(E_1|X_1)P(X_2|X_1)P(E_2|X_2)P(X_3|X_2)P(E_3|X_3)$$

#### Chain Rule and HMMs

• From the chain rule, every joint distribution over  $X_1, E_1, \dots, X_T, E_T$  can be written as:

$$P(X_1, E_1, \dots, X_T, E_T) = P(X_1)P(E_1|X_1) \prod_{t=2}^T P(X_t|X_1, E_1, \dots, X_{t-1}, E_{t-1})P(E_t|X_1, E_1, \dots, X_{t-1}, E_{t-1}, X_t)$$

- Assuming that for all t:
  - State independent of all past states and all past evidence given the previous state, i.e.:

$$X_t \perp \!\!\! \perp X_1, E_1, \ldots, X_{t-2}, E_{t-2}, E_{t-1} \mid X_{t-1}$$

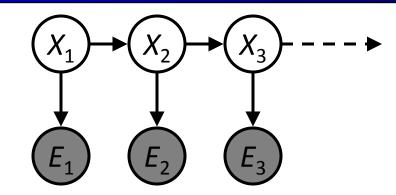

■ Evidence is independent of all past states and all past evidence given the current state, i.e.:

$$E_t \perp \!\!\! \perp X_1, E_1, \ldots, X_{t-2}, E_{t-2}, X_{t-1}, E_{t-1} \mid X_t$$

gives us the expression posited on the earlier slide:

$$P(X_1, E_1, \dots, X_T, E_T) = P(X_1)P(E_1|X_1)\prod_{t=2}^{T} P(X_t|X_{t-1})P(E_t|X_t)$$

### Implied Conditional Independencies

Many implied conditional independencies, e.g.,

$$E_1 \perp \!\!\! \perp X_2, E_2, X_3, E_3 \mid X_1$$

- To prove them
  - Approach 1: follow similar (algebraic) approach to what we did in the Markov models lecture
  - Approach 2: directly from the graph structure (3 lectures from now)
    - lacktriangle Intuition: If path between U and V goes through W, then  $U \perp\!\!\!\!\perp V \mid W$  [Some fineprint later

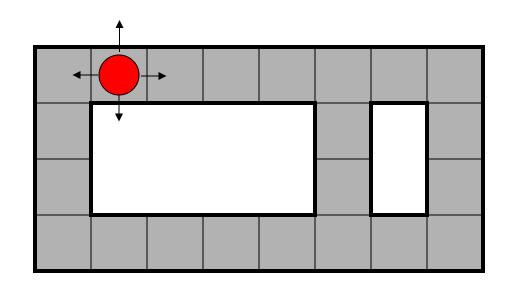

### Real HMM Examples

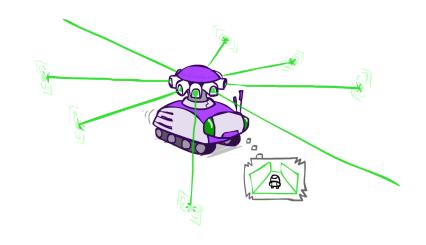

- Speech recognition HMMs:
  - Observations are acoustic signals (continuous valued)
  - States are specific positions in specific words (so, tens of thousands)
- Machine translation HMMs:
  - Observations are words (tens of thousands)
  - States are translation options
- Robot tracking:
  - Observations are range readings (continuous)
  - States are positions on a map (continuous)

# Filtering / Monitoring

- Filtering, or monitoring, is the task of tracking the distribution  $B_t(X) = P_t(X_t \mid e_1, ..., e_t)$  (the belief state) over time
- We start with  $B_1(X)$  in an initial setting, usually uniform
- As time passes, or we get observations, we update B(X)
- The Kalman filter was invented in the 60's and first implemented as a method of trajectory estimation for the Apollo program

Example from Michael Pfeiffer

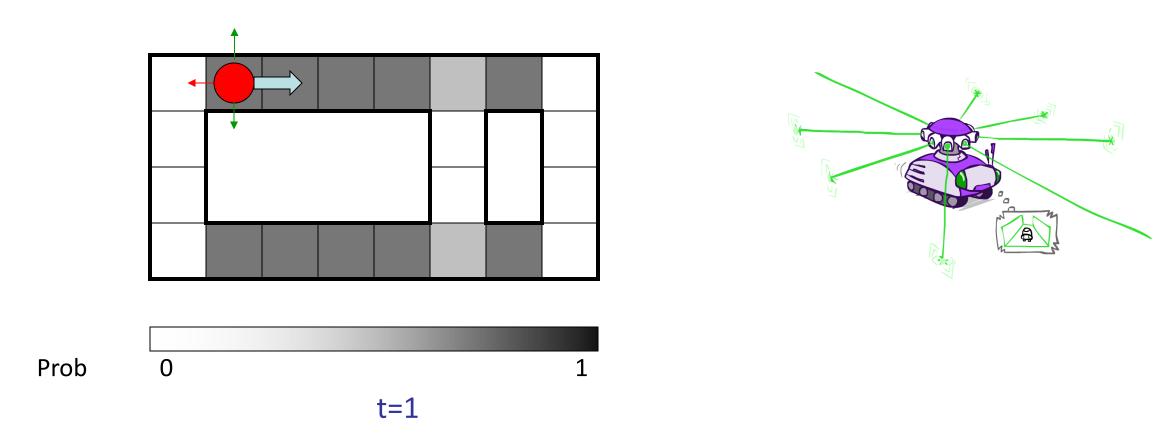

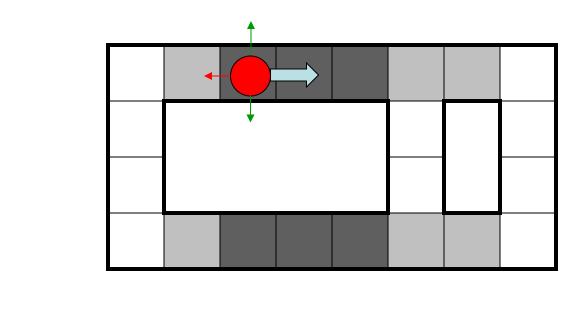

Sensor model: can read in which directions there is a wall, never more than 1 mistake

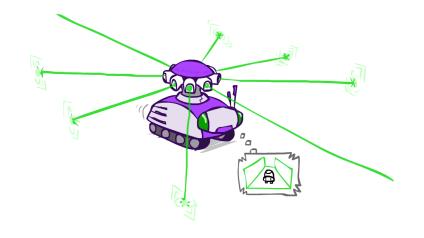

Motion model: may not execute action with small prob.

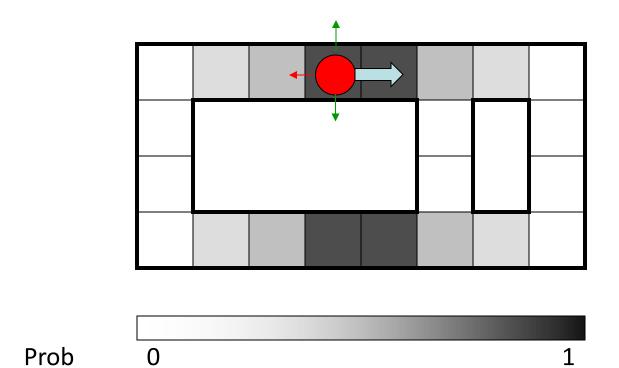

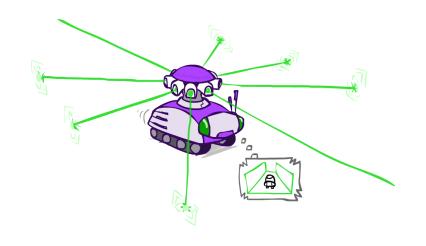

Lighter grey: was possible to get the reading, but less likely b/c required 1 mistake

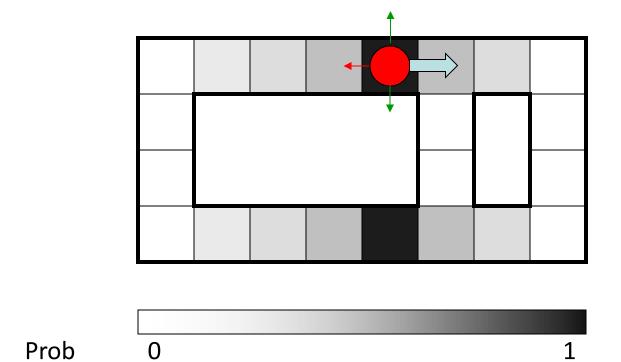

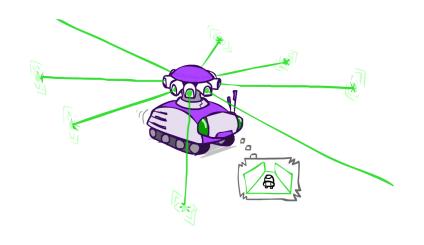

Prob

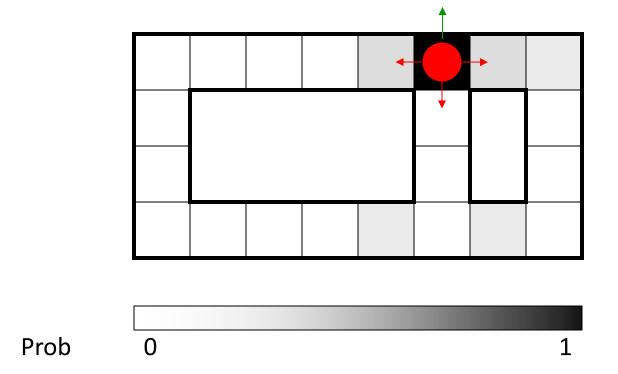

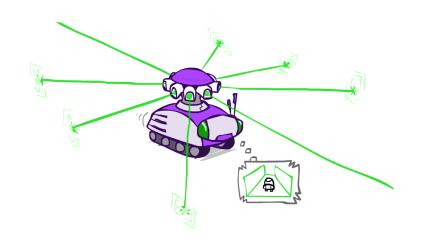

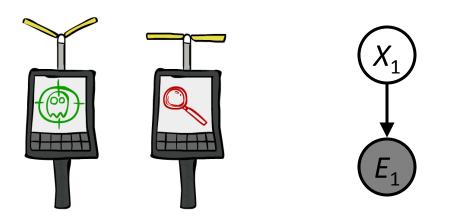

#### Inference: Base Cases

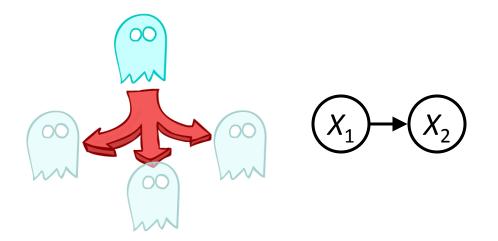

$$P(X_1|e_1)$$

$$P(x_1|e_1) = P(x_1, e_1)/P(e_1)$$

$$\propto_{X_1} P(x_1, e_1)$$

$$= P(x_1)P(e_1|x_1)$$

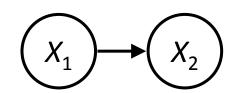

$$P(x_2) = \sum_{x_1} P(x_1, x_2)$$
$$= \sum_{x_1} P(x_1) P(x_2 | x_1)$$

 $P(X_2)$ 

## Passage of Time

Assume we have current belief P(X | evidence to date)

$$B(X_t) = P(X_t|e_{1:t})$$

Then, after one time step passes:

$$P(X_{t+1}|e_{1:t}) = \sum_{x_t} P(X_{t+1}, x_t|e_{1:t})$$

$$= \sum_{x_t} P(X_{t+1}|x_t, e_{1:t}) P(x_t|e_{1:t})$$

$$= \sum_{x_t} P(X_{t+1}|x_t) P(x_t|e_{1:t})$$

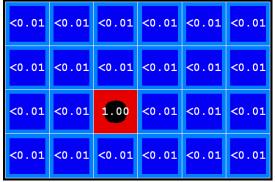

Or compactly:

$$B'(X_{t+1}) = \sum_{x_t} P(X'|x_t)B(x_t)$$

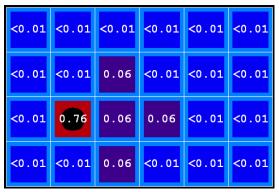

- Basic idea: beliefs get "pushed" through the transitions
  - With the "B" notation, we have to be careful about what time step t the belief is about, and what evidence it includes

### Example: Passage of Time

As time passes, uncertainty "accumulates"

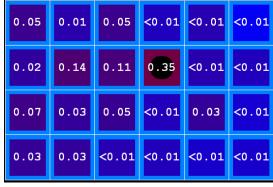

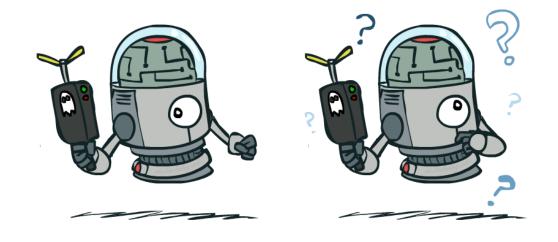

T = 2

(Transition model: ghosts usually go clockwise)

$$T = 5$$

#### Observation

Assume we have current belief P(X | previous evidence):

$$B'(X_{t+1}) = P(X_{t+1}|e_{1:t})$$

Then, after evidence comes in:

$$P(X_{t+1}|e_{1:t+1}) = P(X_{t+1}, e_{t+1}|e_{1:t})/P(e_{t+1}|e_{1:t})$$

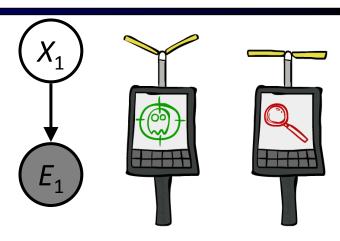

$$\propto_{X_{t+1}} P(X_{t+1}, e_{t+1}|e_{1:t})$$

$$= P(e_{t+1}|e_{1:t}, X_{t+1})P(X_{t+1}|e_{1:t})$$

$$= P(e_{t+1}|X_{t+1})P(X_{t+1}|e_{1:t})$$

Or, compactly:

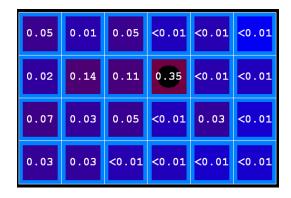

$$B(X_{t+1}) \propto_{X_{t+1}} P(e_{t+1}|X_{t+1})B'(X_{t+1})$$

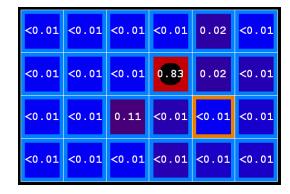

- Basic idea: beliefs "reweighted" by likelihood of evidence
- Unlike passage of time, we have to renormalize

## **Example: Observation**

As we get observations, beliefs get reweighted, uncertainty "decreases"

Before observation

After observation

 $B(X) \propto P(e|X)B'(X)$ 

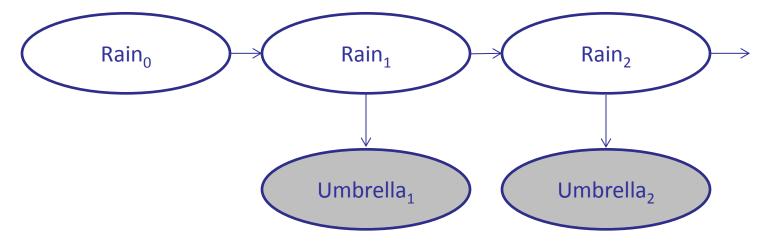

## Example: Weather HMM

$R_{t}$	R <sub>t+1</sub>	$P(R_{t+1} R_t)$
+r	+r	0.7
+r	-r	0.3
-r	+r	0.3
-r	-r	0.7

$R_{t}$	U <sub>t</sub>	$P(U_t   R_t)$
+r	+u	0.9
+r	-u	0.1
-r	+u	0.2
-r	-u	0.8

### The Forward Algorithm

We are given evidence at each time and want to know

$$B_t(X) = P(X_t|e_{1:t})$$

We can derive the following updates

$$P(x_{t}|e_{1:t}) \propto_{X} P(x_{t}, e_{1:t})$$

$$= \sum_{x_{t-1}} P(x_{t-1}, x_{t}, e_{1:t})$$

$$= \sum_{x_{t-1}} P(x_{t-1}, e_{1:t-1}) P(x_{t}|x_{t-1}) P(e_{t}|x_{t})$$

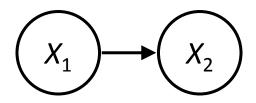

$$= P(e_{t}|x_{t}) \sum_{x_{t-1}} P(x_{t}|x_{t-1}) P(x_{t-1}, e_{1:t-1})$$

We can normalize as we go if we want to have P(x|e) at each time step, or just once at the end...

## Online Belief Updates

- Every time step, we start with current P(X | evidence)
- We update for time:

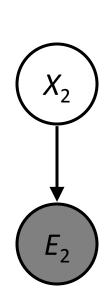

$$P(x_t|e_{1:t-1}) = \sum_{x_{t-1}} P(x_{t-1}|e_{1:t-1}) \cdot P(x_t|x_{t-1})$$

We update for evidence:

$$P(x_t|e_{1:t}) \propto_X P(x_t|e_{1:t-1}) \cdot P(e_t|x_t)$$

- The forward algorithm does both at once (and doesn't normalize)
- Problem: space is |X| and time is |X|<sup>2</sup> per time step
