More Linux - Piping and Redirection

Outline

- File and Directory Permissions
- File Content
- Finding Files
- Sorting Files
- File Compression
- Processes
- Pipes
- Input/Output Redirection
- Controlling Processes

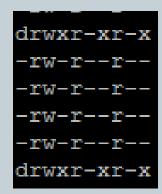

File and Directory Permissions

Permission	File	Directory
read	User can look at the contents of the file	User can list the files in the directory
write	User can modify the contents of the file	User can create new files and remove existing files in the directory
execute	User can use the filename as a Linux command	User can change into the directory, but cannot list the files unless they have read permission. User can read files if they have read permission on them.

Changing File Permissions

- chmod options files
- Two forms:
 - o options as a sequence of three octal digits
 - first digit is for owner permissions
 - second for group permissions
 - third is for everyone else

chmod 600 private.txt

-rw-----

Permission	Binary	Octal
	000	0
X	001	1
-W-	010	2
-wx	011	3
r	100	4
r-x	101	5
rw-	110	6
rwx	111	7

Changing File Permissions

- chmod options files
- Second form:
 - o *options* as a sequence of symbols
 - o u user, g group, o, other, a all, r read, w write, x execute
 - o "+" − add permission, "-" delete permission
 - chmod ug=rw,o-rw,a-x private.txt
 -rw-rw----

File Contents

- file filename(s)
 - Analyzes a files contents

webpage.html: HTML document text

- head, tail filename
 - o Displays the first or last few lines in a file
 - You can specify number of lines

```
$ tail -20 messages.txt ←
$ head -5 messages.txt ←
```

File Contents

- od options filename
 - Displays binary file contents in different formats

```
$ cat hello.txt \\
hello world
$ od -c hello.txt \\
00000000 h e l l o w o r l d \n
0000014
$ od -x hello.txt \\
00000000 6865 6c6c 6f20 776f 726c 640a
0000014
```

Finding Files

• find directory -name targetfile -print

```
$ find /home -name "*.txt" -print 2>/dev/null ←
```

which command

```
$ which ls ←
/bin/ls
```

locate string

```
$ locate ".txt" ←
```

Finding Text in Files

- grep options patterns files
- Stands for General Regular Expression Print

The caret `^' and the dollar sign `\$' are special characters that match the beginning and end of a line respectively. The dot '.' matches any character. So

```
$ grep ^..[1-z]$ hello.txt ←
```

matches any line in hello.txt that contains a three character sequence that ends with a lowercase letter from 1 to z.

- egrep options patterns files
- Stands for Extended grep
 - Can join expressions with or '|', can use parentheses for grouping
 - Can use other regular expression operators:
 - \times ?, *, +, {N}, {N,}, {N,M}

Sorting File Contents

sort filenames

```
$ sort input1.txt input2.txt > output.txt ←
outputs the sorted concentenation of files input1.txt and input2.txt to the file output.txt.
```

- uniq filename
 - Removes duplicate adjacent lines in a file, handy when combined with sort:

```
$ sort input.txt | uniq > output.txt ←
```

File Backup – tar – and Compression

- To create a disk file tar archive:
 - o tar -cvf *archivename filenames*
- To list the contents of an archive:
 - o tar -tvf *archivename*
- To restore files from a tar archive:
 - o tar -xvf archivename
- To compress files in a tar archive:
 - o compress filename
- Or:
 - o gzip filename

Processes

- A process is a program in execution
 - o Each has a unique process identifier (PID)
 - The first process started when Linux boots is init
 - X All processes are children of init
 - o Can be any executing program:
 - X Your running Java program
 - ■ A command you are executing
 - ➤ A daemon started by the Linux kernel
 - × Etc.

Pipes

- Pipe operator '|' creates concurrently executing processes which pass data directly to one another
- Used to combine system utilities together

```

Input/Output Redirection

- Linux treats everything as a file
 - Including standard input (keyboard), standard output (screen)
 and standard error (also the screen)
 - We can redirect input or output from these "files" using the redirection operators < and >
 - ▼ The "arrow" points to where the input/output goes

Redirecting Standard Output

 To redirect standard output to a file instead of a screen, use the > operator:

```
$ echo hello \(\lefta\)
hello
$ echo hello > output \(\lefta\)
$ cat output \(\lefta\)
hello
```

- This will create a new blank file each time
 - If you want to append to a file, use >>

```
$ echo bye >> output ←
$ cat output ←
hello
bye
```

Redirecting Standard Error to a File

- Standard input (0), standard output (1) and standard error (2) have those numbers associated with them
- To output any error messages to a file, use 2>

```
$ cat nonexistent 2>errors ←
$ cat errors ←
cat: nonexistent: No such file or directory
$
```

- To output results to one file and errors to another:
 - o find . –print 1>files 2>errors
- This is very handy when you are compiling a program and you get a whole list of error messages

Redirecting Standard Input

 Input will be read from a file rather than from keyboard input

```
$ cat < output ←
hello
bye</pre>
```

- Remember the "arrow" points to where the data will go
 - In this case it will come from a file and go into the command "cat"

Controlling Processes

- You can run several processes at the same time
 - Processes can run in the foreground (the thing you currently see) or in the background (you don't see it running, but it is)
- To start a process in the background, use & at the end of the command line:

```
$ find / -print 1>output 2>errors & ←
[1] 27501
$
```

- [1] is the job number and 27501 is the process id (PID)
- Note: if your background process prints to the screen, it will show up as you're doing something else

Controlling Processes

- To put the current process in the background:
 - Type Ctrl-Z
- To bring a background process to the foreground:
 - o fg %<job number>
- To see all of the processes you have running:
 - o ps

```
$ ps  TTY TIME CMD

17717 pts/10 00:00:00 bash

27501 pts/10 00:00:01 find

27502 pts/10 00:00:00 ps
```

Controlling Processes

- What if you have a process you want to stop? (Maybe it's in an infinite loop, maybe... it's just a bad process?)
 - You can use:
 - x kill %<job number> OR
 - × kill <PID>
 - These are polite ways of asking the process to terminate
 - Processes are not always polite in return...
 - × kill -9 <PID>
 - This will kill them on contact

Summary

- File and Directory Permissions
- File Content
- Finding Files
- Sorting Files
- File Compression
- Processes
- Pipes
- Input/Output Redirection
- Controlling Processes
